Linear Regression: Correlation

You can describe the overall pattern of a scatterplot by the form, direction, and strength of the relationship between the two variables.

- The form of a scatterplot is generally described as either linear or curved.
- The direction (or association) of a scatterplot is described as positive if the scatterplot slopes upward as we move from left to right, as negative if the scatterplot slopes downward as we move from left to right, or as none if the direction is neither positive nor negative.
- The strength of the relationship between two variables shown in a scatterplot is determined by how closely the points follow a clear form. Use the words strong, moderate, or weak to describe the strength.

Here are some examples of how to describe scatterplots:

linear, positive
moderate

linear, neither,
strong

linear, negative
strong w/ an outlier

curved, positive
moderate

curved, negative
strong

non-linear, neither
weak

2 Match each of the following descriptions to a scatterplot shown below.

- a. Linear, negative, moderate
- b. Curved, negative, moderate
- c. Linear, positive, weak

- d. Curved, positive, strong
- e. Linear, positive, moderate

I.

II.

III.

IV.

V.

Bottom of page

Correlation Coefficient / r-value : tells you how strong & what direction the data is.

r-values closer to 1 & -1 are the strongest
r-values closer to 0 is weak
